

# The definition of the $A_2^{(2)+}$ State Multipoles

Mikhail Lemeshko and Millard H. Alexander

## I. GENERALITIES

Following Orr-Ewing and Zare,[1] we define the  $A_2^{(2)+}(J)$  state multipole as

$$A_2^{(2)+}(J) = 2^{-1/2} \left[ \mathcal{A}_2^{(2)}(J) + \mathcal{A}_{-2}^{(2)}(J) \right], \quad (1)$$

where [Eq. (39) of Ref. 1]

$$\mathcal{A}_q^{(k)}(J) = \frac{(-1)^q c(k)}{\langle JM | \mathbf{J}^2 | JM \rangle^{k/2}} \frac{(J \parallel \mathbf{J}^{(k)} \parallel J)}{\sqrt{2k+1}} \rho_{-q}^{(k)}(J)$$

In addition, the spherical tensor components of the density matrix are defined as [Eq. (21) of Ref. [1]]

$$\rho_q^{(k)}(J) = \sum_{M, M'} (-1)^{J-M'} (2k+1)^{1/2} \begin{pmatrix} J & k & J \\ -M & -q & M' \end{pmatrix} \rho_{M'M}$$

In a collision experiment, the transition out of initial rotational level  $J''$  into final rotational level  $J$  at scattering angle  $\theta$  is fully described by the  $M$ -resolved (complex) scattering amplitudes  $f_{J''M'' \rightarrow JM}(\theta)$ . (We will suppress the scattering angle unless explicitly needed). In terms of these, the  $\{M, M'\}^{th}$  element of the density matrix for final rotational level  $J$  at scattering angle  $\theta$  is

$$\rho_{M'M} = \sum_{M''} f_{J''M'' \rightarrow JM'}^* f_{J''M'' \rightarrow JM} / \sum_{M'', M'} |f_{J''M'' \rightarrow JM'}|^2 \quad (2)$$

The denominator is chosen so that

$$\text{Tr}(\rho_{M'M}) = \sum_M \rho_{MM} = 1$$

We assume that the scattering amplitude is dimensionless, so that the degeneracy-averaged  $J'' \rightarrow J$  differential cross section (the sum over all final projection states and average over

all initial projection states of the  $J''M'' \rightarrow JM'$  differential cross section) is

$$\frac{d\sigma(J'' \rightarrow J)}{d\Omega} = \frac{1}{(2J'' + 1)k_{J''}^2} \sum_{M'', M'} |f^{J''M'' \rightarrow JM'}|^2 \quad (3)$$

where  $k_{J''}$  is the initial wavevector. We also note, as one might anticipate, that the density matrix is Hermitian

$$\rho_{M'M}^* = \rho_{MM'} \quad (4)$$

Note, again, that the rotational density matrix state multipoles of the scattered molecules are functions of the scattering angle.

In the particular case where  $k = 2$  and  $q = \pm 2$  we have

$$\begin{aligned} \mathcal{A}_2^{(2)}(J) &= \frac{(-1)^2 c(2)}{\langle JM | \mathbf{J}^2 | JM \rangle^{2/2}} \frac{(J \parallel \mathbf{J}^{(2)} \parallel J)}{\sqrt{5}} \rho_{-2}^{(2)}(J) \\ &= \left[ \frac{(2J-1)(2J+1)(2J+3)}{5J(J+1)} \right]^{1/2} \rho_{-2}^{(2)}(J) \\ &= (-1)^J \left[ \frac{(2J-1)(2J+1)(2J+3)}{J(J+1)} \right]^{1/2} \sum_{MM'} (-1)^{-M'} \begin{pmatrix} J & 2 & J \\ -M & 2 & M' \end{pmatrix} \rho_{M'M} \quad (5) \end{aligned}$$

Thus, from Eq. (1) and using

$$\langle JM | \mathbf{J}^2 | JM \rangle = J(J+1),$$

and (see p. 231 of Ref. [2])

$$(J \parallel \mathbf{J}^{(2)} \parallel J) = \left[ \frac{J(J+1)(2J-1)(2J+1)(2J+3)}{6} \right]^{1/2}$$

we have

$$\begin{aligned} \mathcal{A}_2^{(2)+}(J) &= (-1)^J \left[ \frac{(2J-1)(2J+1)(2J+3)}{2J(J+1)} \right]^{1/2} \\ &\quad \times \sum_{MM'} (-1)^{-M'} \left[ \begin{pmatrix} J & 2 & J \\ -M & 2 & M' \end{pmatrix} + \begin{pmatrix} J & 2 & J \\ -M & -2 & M' \end{pmatrix} \right] \rho_{M'M} \quad (6) \end{aligned}$$

In fact, the triangular relation contained in the  $3j$  symbols restricts  $M'$  to a single value

( $M' = M + 2$  or  $M' = M - 2$ ), so that the double sums can be replaced by

$$A_2^{(2)+}(J) = (-1)^J \left[ \frac{(2J-1)(2J+1)(2J+3)}{2J(J+1)} \right]^{1/2} \left[ \sum_{M=-J+2}^J (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & 2 & M-2 \end{pmatrix} \rho_{M,M-2} \right. \\ \left. + \sum_{M=-J}^{J-2} (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & -2 & M+2 \end{pmatrix} \rho_{M,M+2} \right]$$

We can define  $M' = M - 2$  in the first summation, then replace  $M'$  by  $M$ , and use the known symmetries of the  $3j$  symbols to get

$$\begin{aligned} \sum_{M=-J+2}^J (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & 2 & M-2 \end{pmatrix} \rho_{M,M-2} &= \sum_{M'=-J}^{J-2} (-1)^{-M'-2} \begin{pmatrix} J & 2 & J \\ -M'-2 & 2 & M' \end{pmatrix} \rho_{M'+2,M'} \\ &= \sum_{M=-J}^{J-2} (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M-2 & 2 & M \end{pmatrix} \rho_{M+2,M} \\ &= \sum_{M=-J}^{J-2} (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & -2 & M+2 \end{pmatrix} \rho_{M+2,M} \end{aligned}$$

We use this result, and the hermiticity of the density matrix [Eq. (4)], to simplify Eq. (6) to

$$\begin{aligned} A_2^{(2)+}(J) &= (-1)^J \left[ \frac{(2J-1)(2J+1)(2J+3)}{2J(J+1)} \right]^{1/2} \\ &\quad \times \sum_{M=-J}^{J-2} (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & -2 & M+2 \end{pmatrix} (\rho_{M+2,M} + \rho_{M,M+2}) \\ &= (-1)^J \left[ \frac{2(2J-1)(2J+1)(2J+3)}{J(J+1)} \right]^{1/2} \\ &\quad \times \sum_{M=-J}^{J-2} (-1)^{-M} \begin{pmatrix} J & 2 & J \\ -M & -2 & M+2 \end{pmatrix} \mathcal{R}(\rho_{M+2,M}) \end{aligned} \quad (7)$$

where  $\mathcal{R}$  designates the real part of a complex number. From Eq. (2) one can show that

$$\begin{aligned} \mathcal{R}(\rho_{M+2,M}) &= \sum_{M''} [\mathcal{R}(f_{J''M'' \rightarrow JM}) \mathcal{R}(f_{J''M'' \rightarrow JM+2}) + \mathcal{I}(f_{J''M'' \rightarrow JM}) \mathcal{I}(f_{J''M'' \rightarrow JM+2})] \\ &\quad / \sum_{M'',M} |f_{J''M'' \rightarrow JM}|^2 \\ &= \sum_{M''} [\mathcal{R}(f_{J''M'' \rightarrow JM}) \mathcal{R}(f_{J''M'' \rightarrow JM+2}) + \mathcal{I}(f_{J''M'' \rightarrow JM}) \mathcal{I}(f_{J''M'' \rightarrow JM+2})] \\ &\quad / \sum_{M'',M} [\mathcal{R}(f_{J''M'' \rightarrow JM}) \mathcal{R}(f_{J''M'' \rightarrow JM}) + \mathcal{I}(f_{J''M'' \rightarrow JM}) \mathcal{I}(f_{J''M'' \rightarrow JM})] \end{aligned} \quad (8)$$
